

Seisme du Japon 11 Mars, 2011

Main shock (9.1)
and after shocks
with tsunami
(port wave)

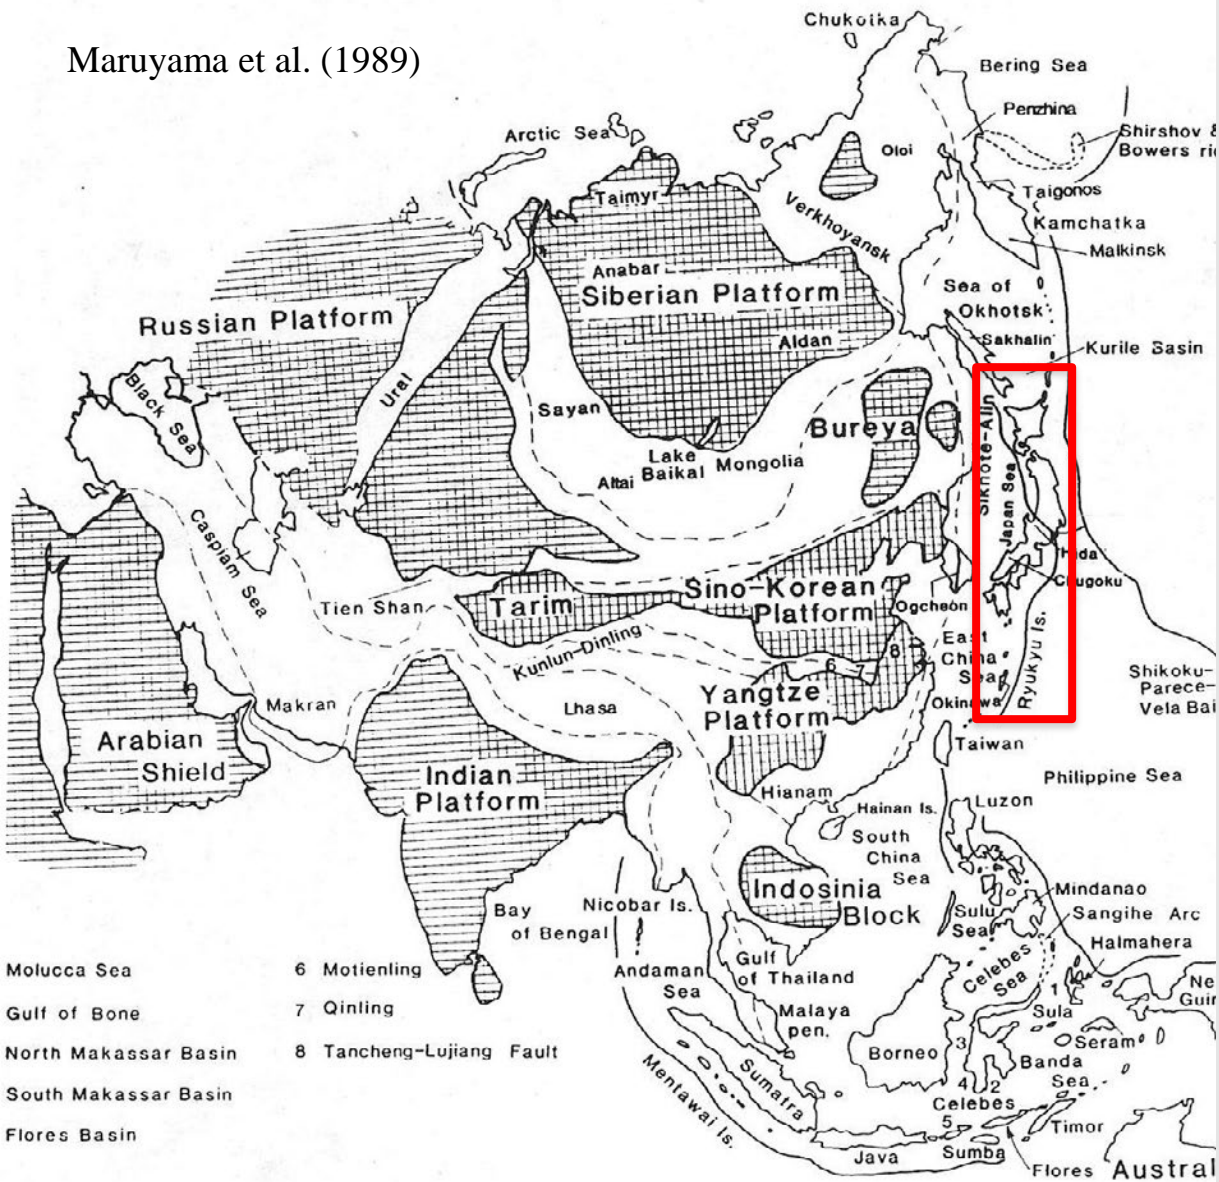

Geotectonic evolution of the Japanese Islands

significance not only for Japan but also for the whole mantle

Yukio Isozaki

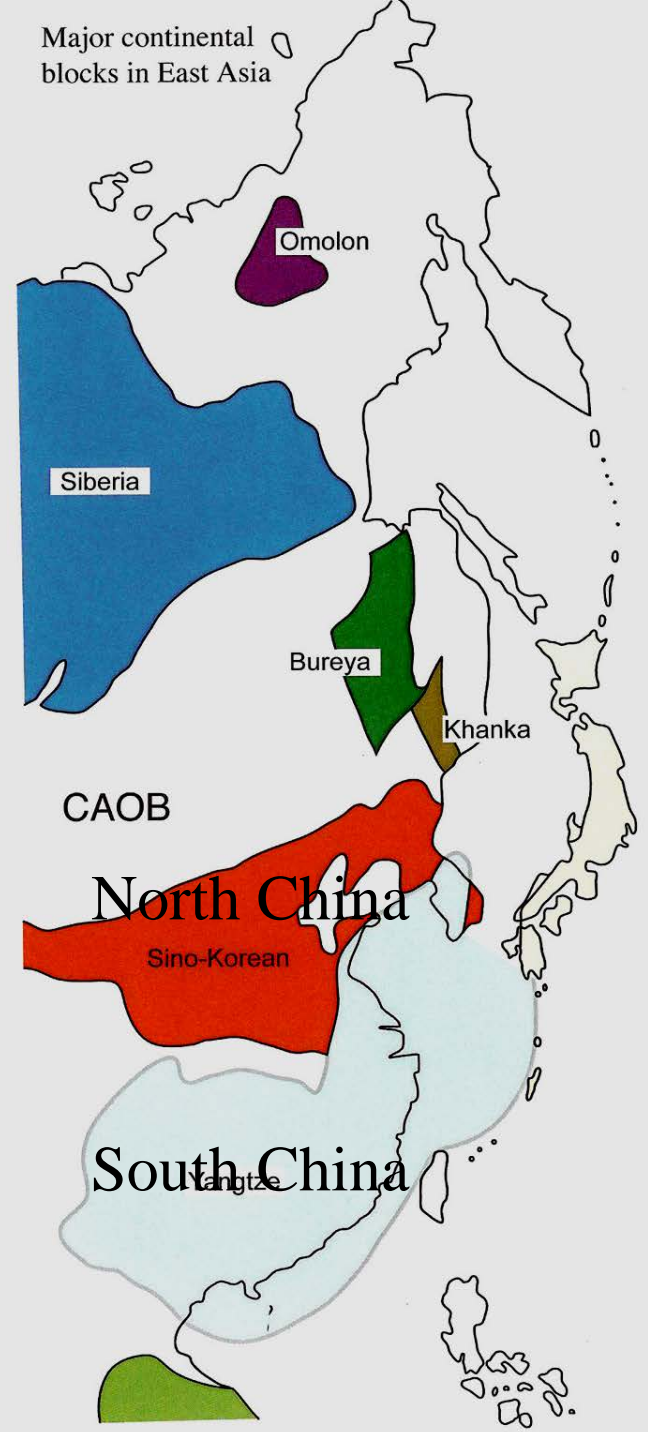

Dept. Earth Science & Astronomy
The University of Tokyo

Maruyama et al. (1989)

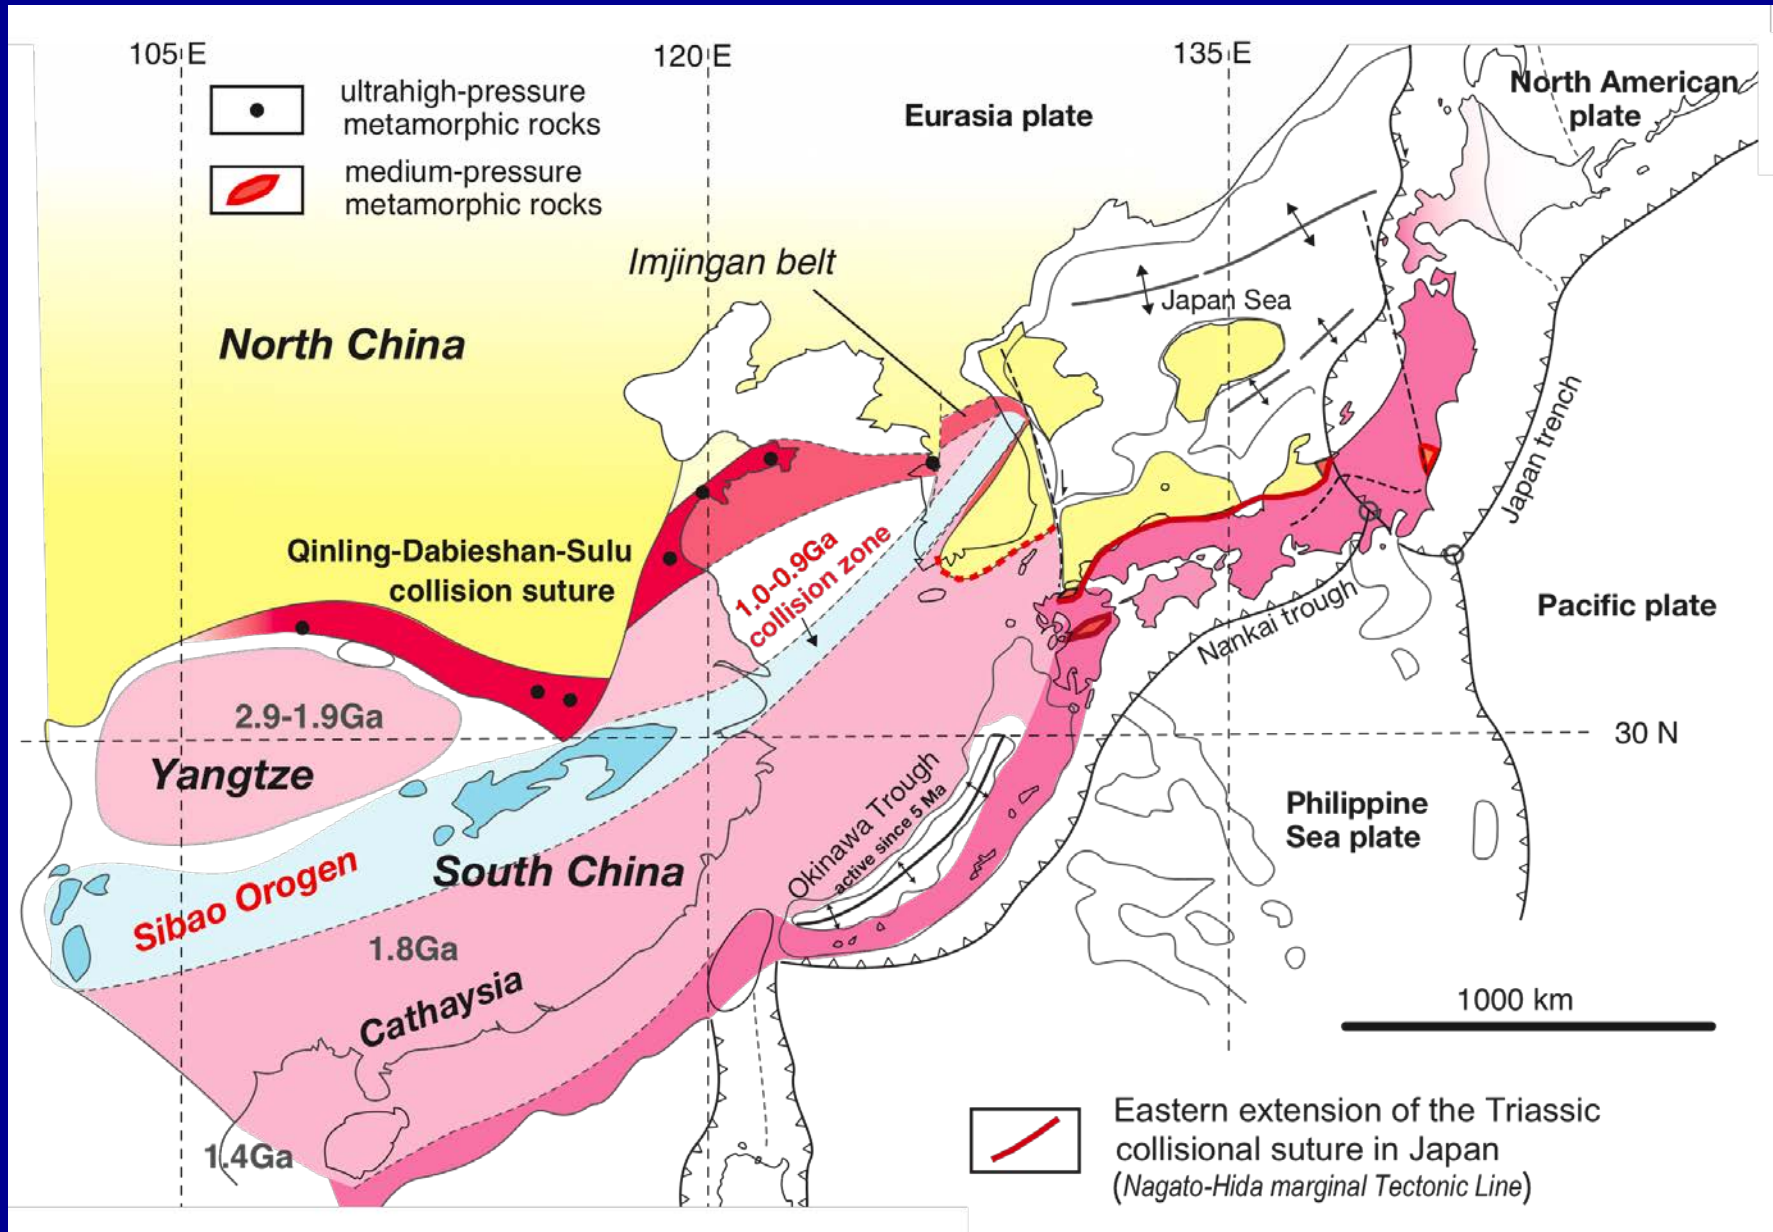

- Molucca Sea
- Gulf of Bone
- North Makassar Basin
- South Makassar Basin
- Flores Basin
- 6 Motientling
- 7 Qinling
- 8 Tancheng-Lujiang Fault

Major continental blocks in East Asia

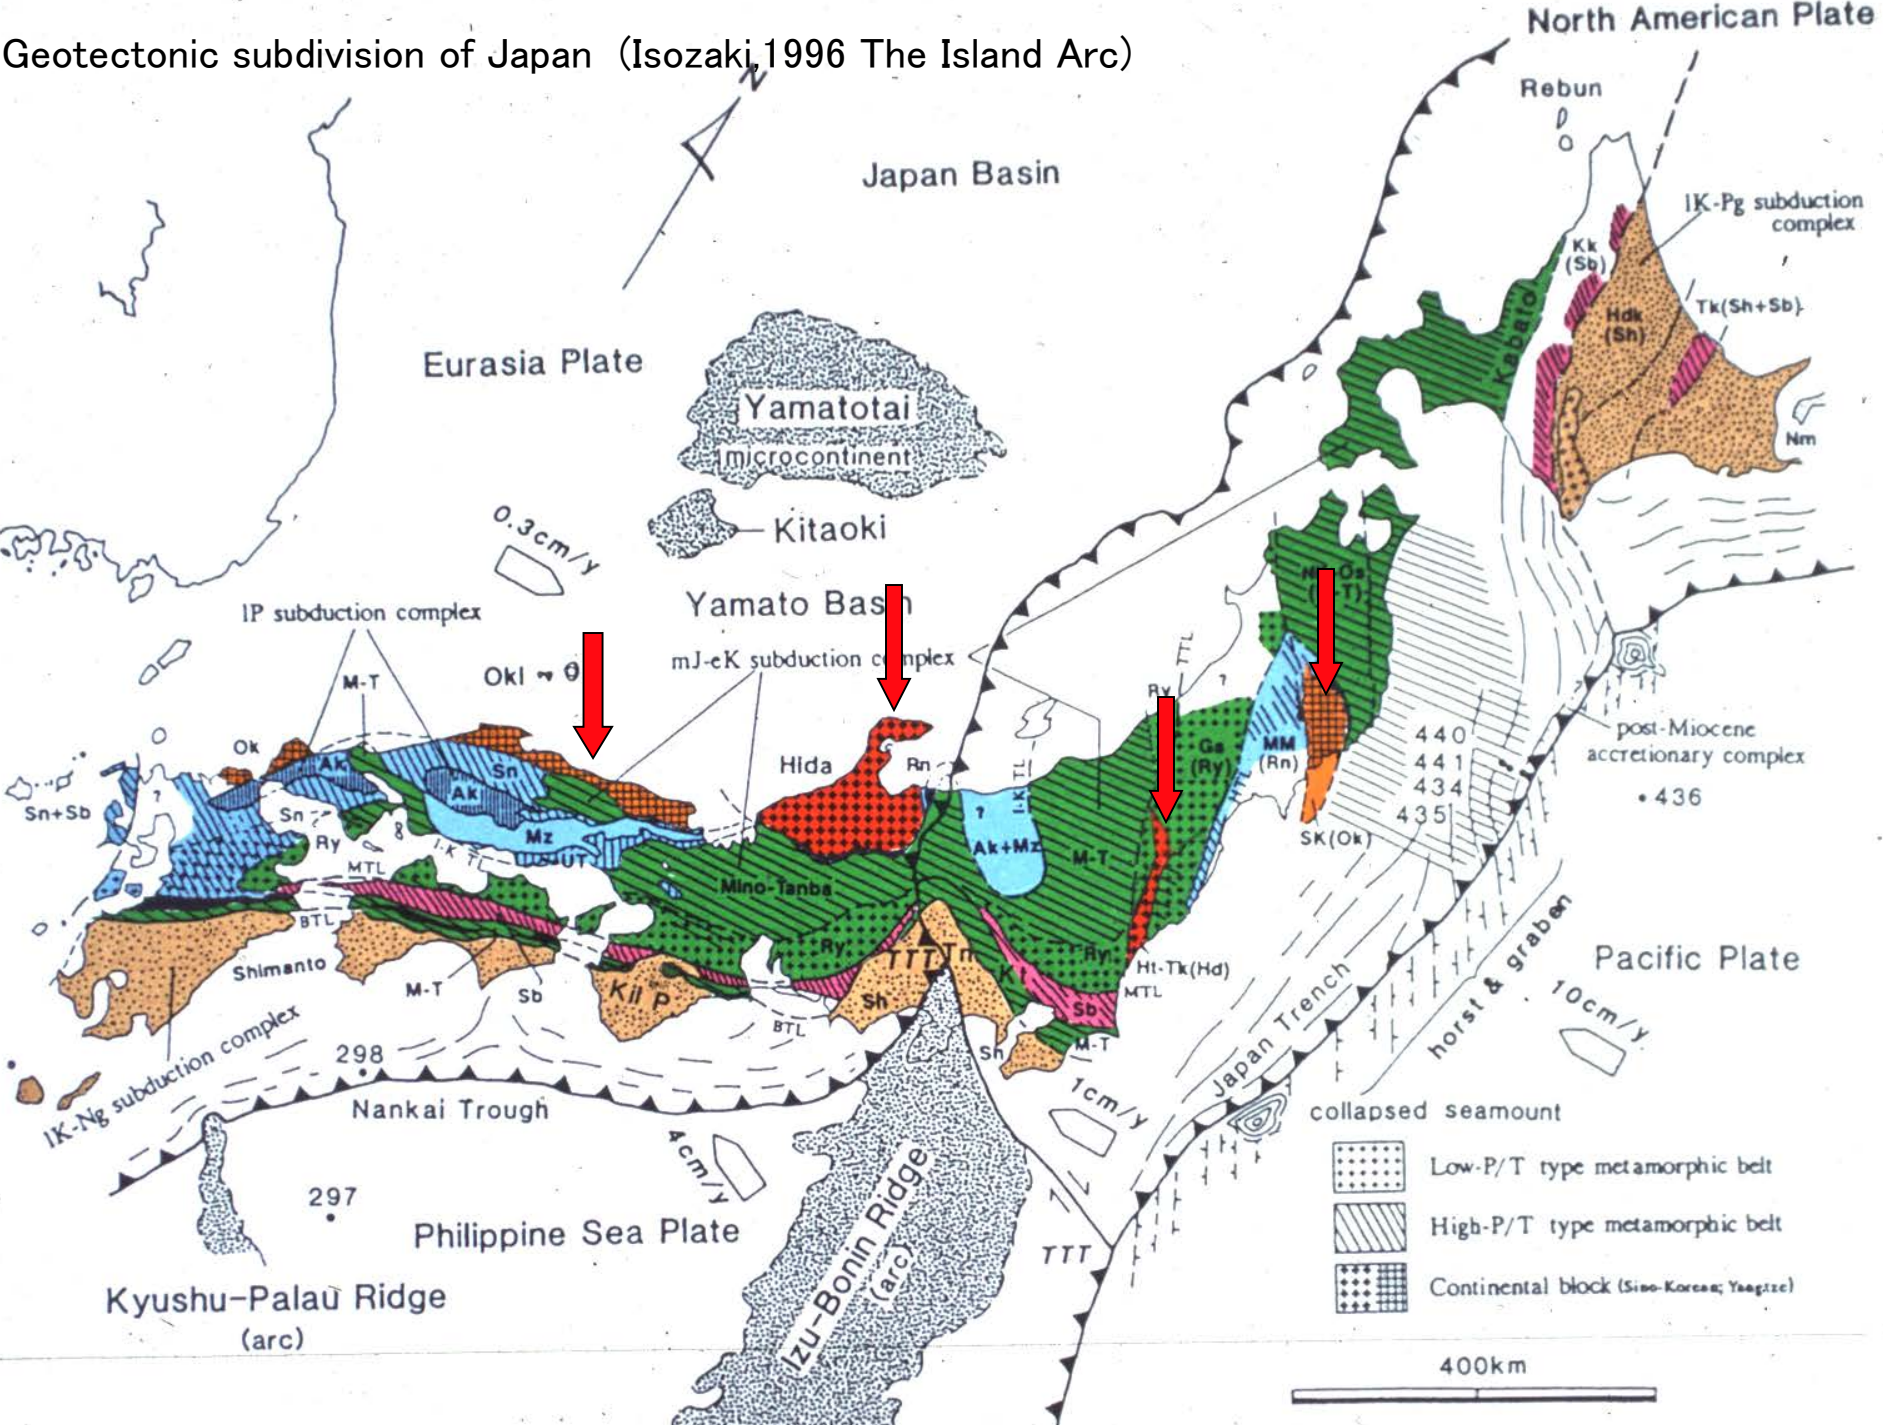

Asia is a composite continent composed of 9-10 blocks

Old Japan along South China (Yangtze) block

ca. 900 million year-long history of the Japanese Islands in 1 minute

Ma: million years ago

birth @a rift: 700 Ma

early growth @passive margin: 700-500 Ma

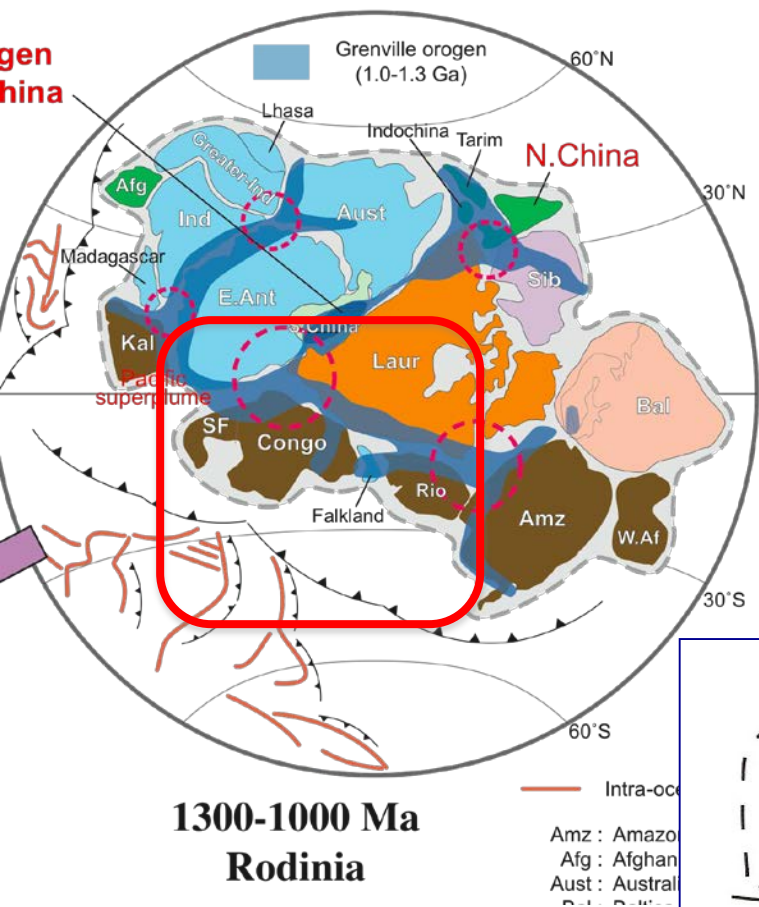

tectonic

conversion: 500 Ma

accretionary growth: 500 Ma-50

MaAP

demise in collision: 50-200 MaAP

700 Ma breakup of the supercontinent Rodinia

(Rino et al., 2009)

birth @ S. China margin
counterpart: western N. America (Laurentia)

“Say Good-bye to Hollywood!”

Initiation of oceanic subduction (500 Ma)

Onset of initial oceanic subduction
(tectonic inversion from passive
margin to active margin) (~500Ma)

essential geologic elements formed along arc–trench system
(Isozaki et al., 2010, 2011)

accretionary complex (AC)

blueschists (high-pressure meta-AC)

fore-arc +back-arc basin sediments

arc granite: factory of continental crust beneath volc. arc

oceanward growth
of continental crust
along active continental margin

net continental growth:
juvenile addition of arc granite

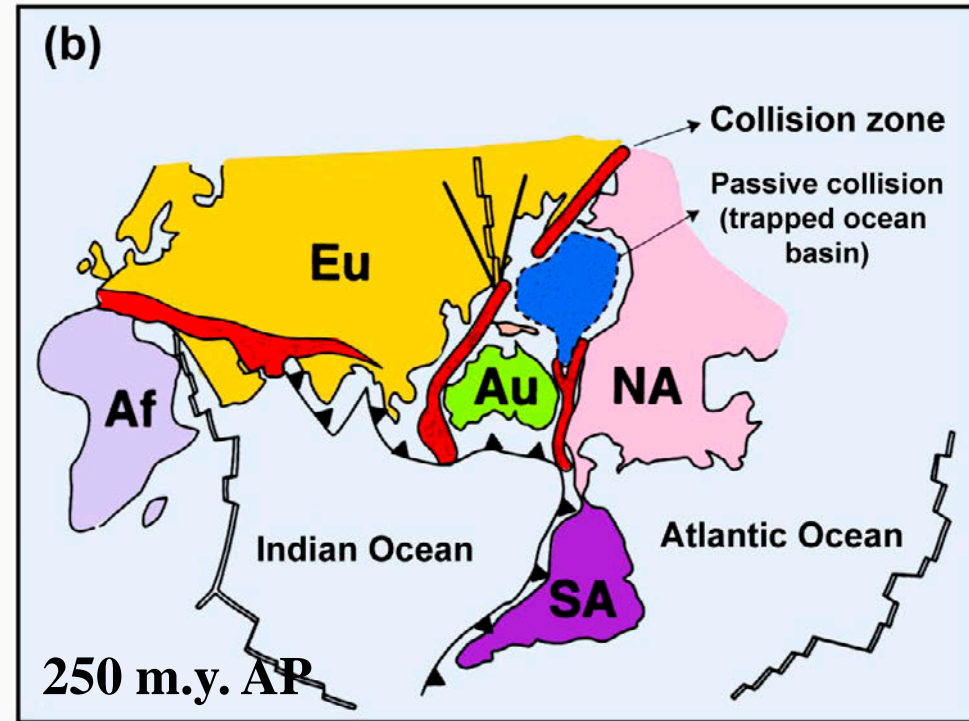

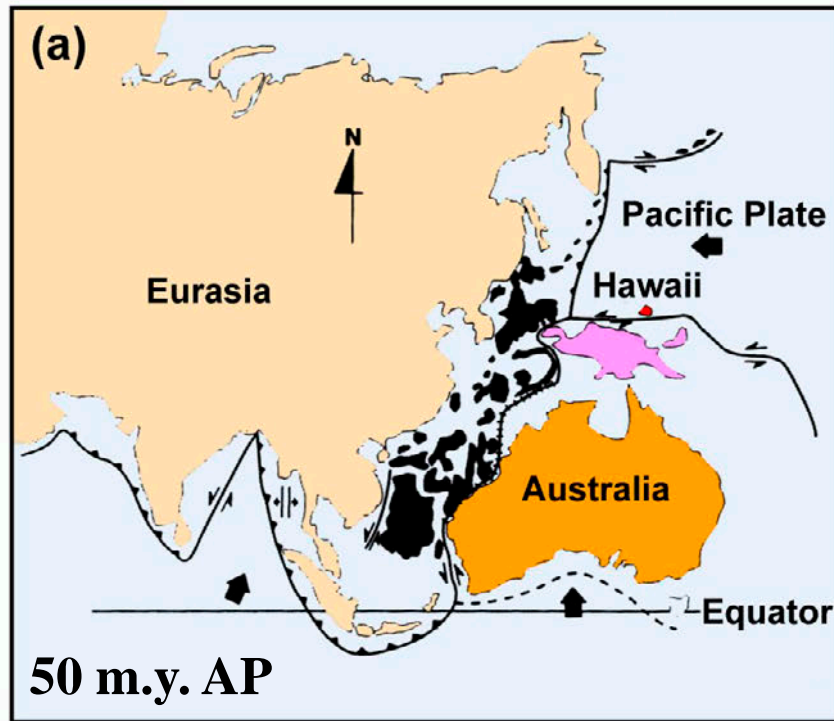

Stepwise oceanward propagation of BS belt and granite belt

lifetime of Pacific Ocean

Grand finale @ ca. 200 m.y. after present

Geography of Asia at (a) 50 million years and (b) 250 million years after present

end of Japan = end of the Pacific Ocean
= formation of the next supercontinent

America + Asia = *Amasia*

Dewey & Bird (1970) Jour. Geophys. Res.

highly cited classic paper on mountain building processes
based on plate tectonics

collision-type vs. Cordilleran-type

Alpine-Himalaya
Variscan/Hercynian
Caledonian

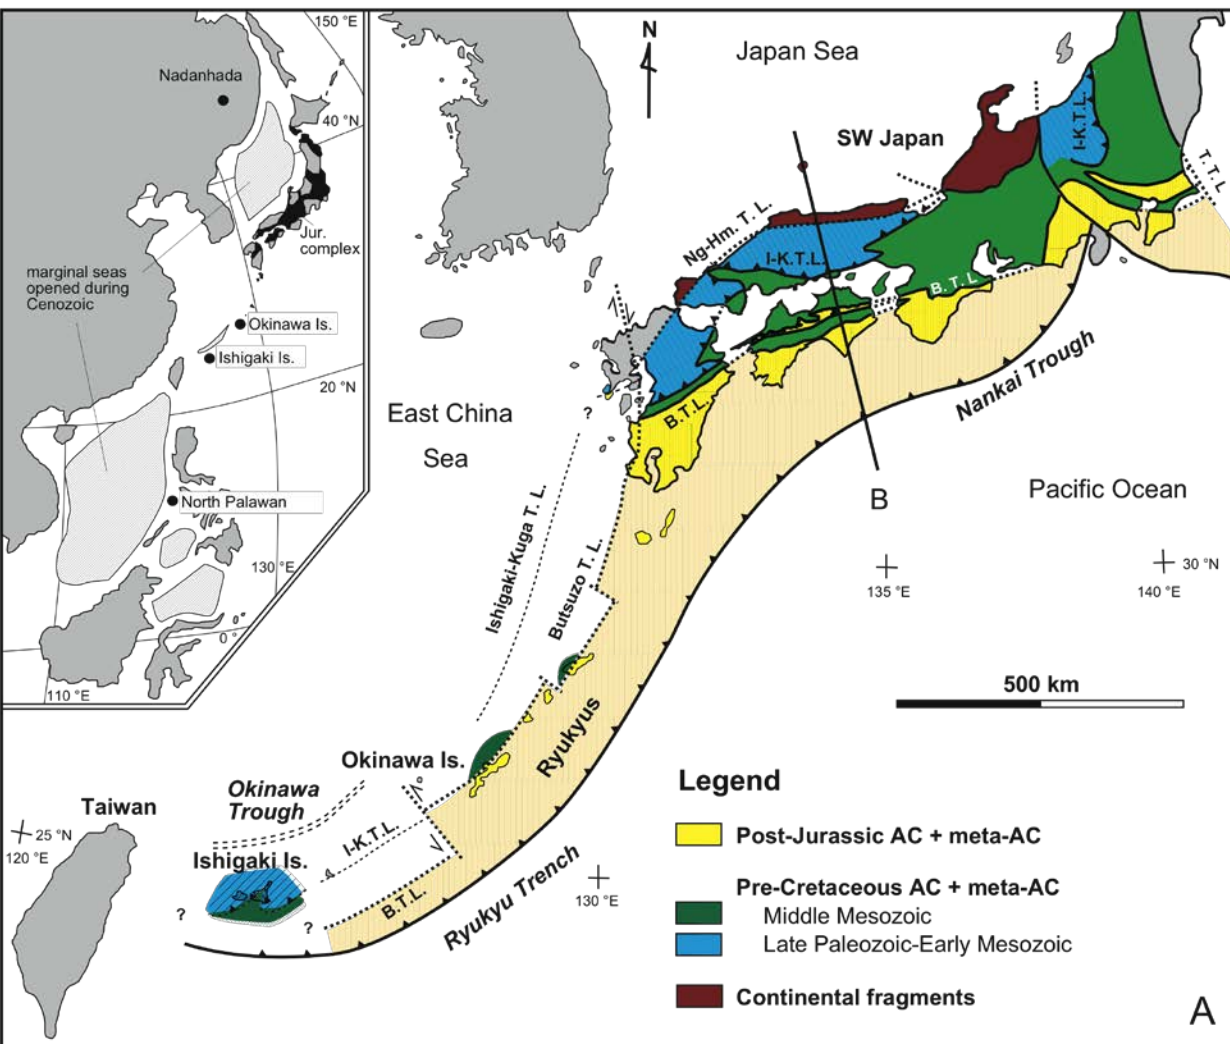

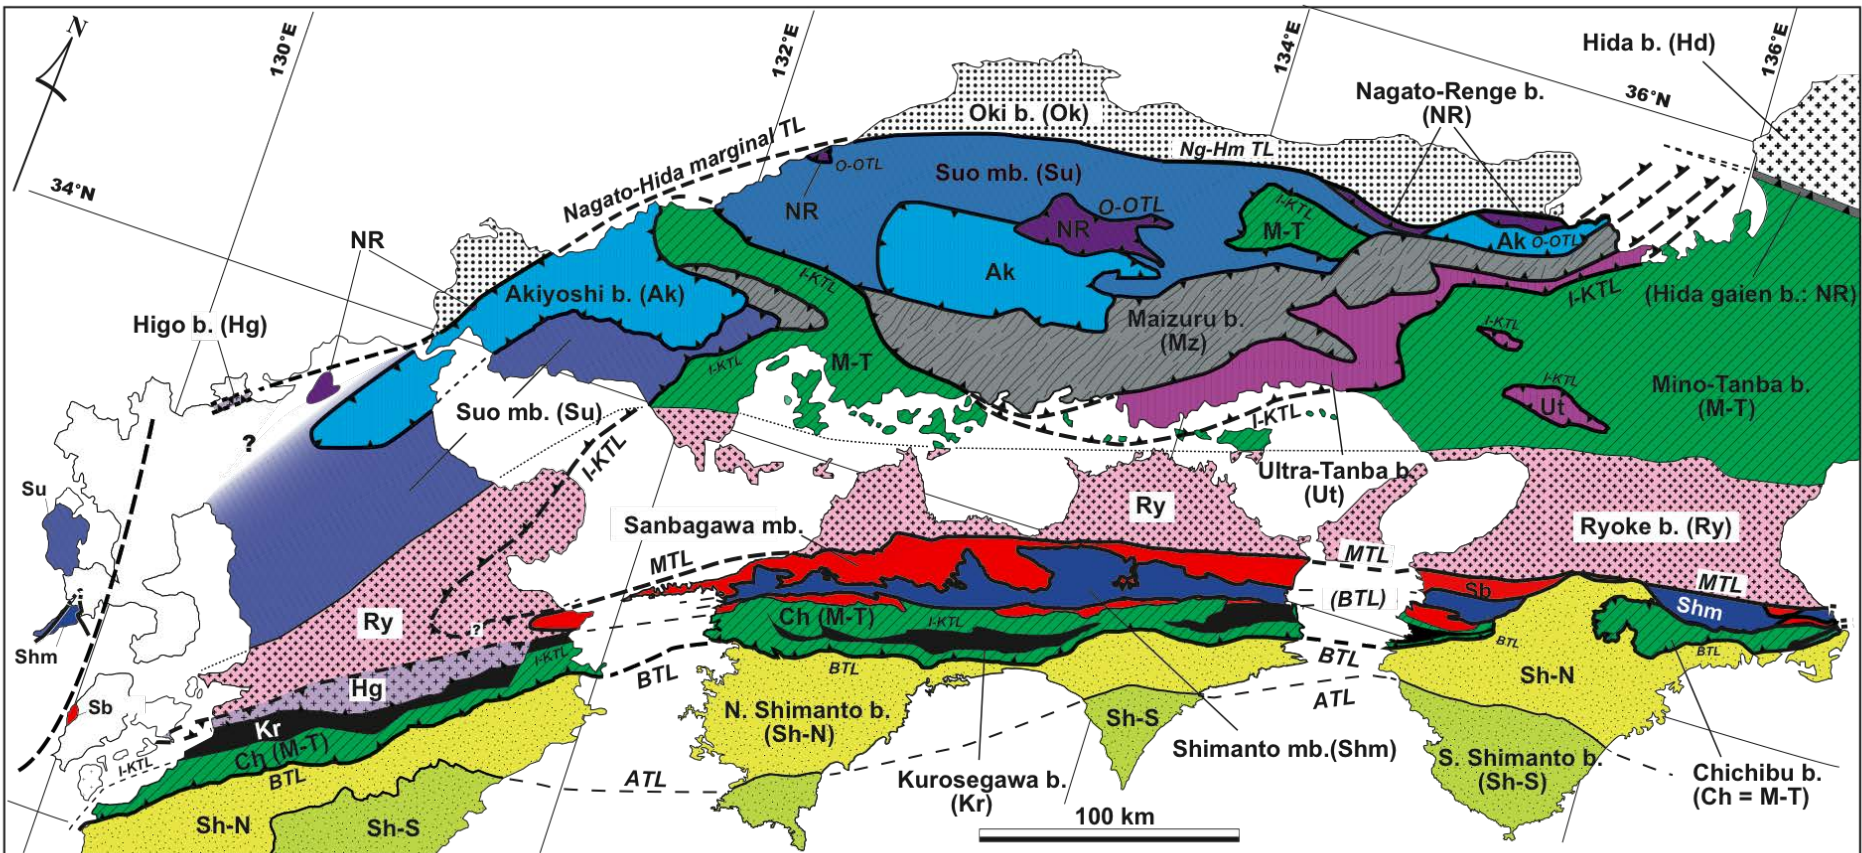

California, B.C.,
Japan
circum-Pacific

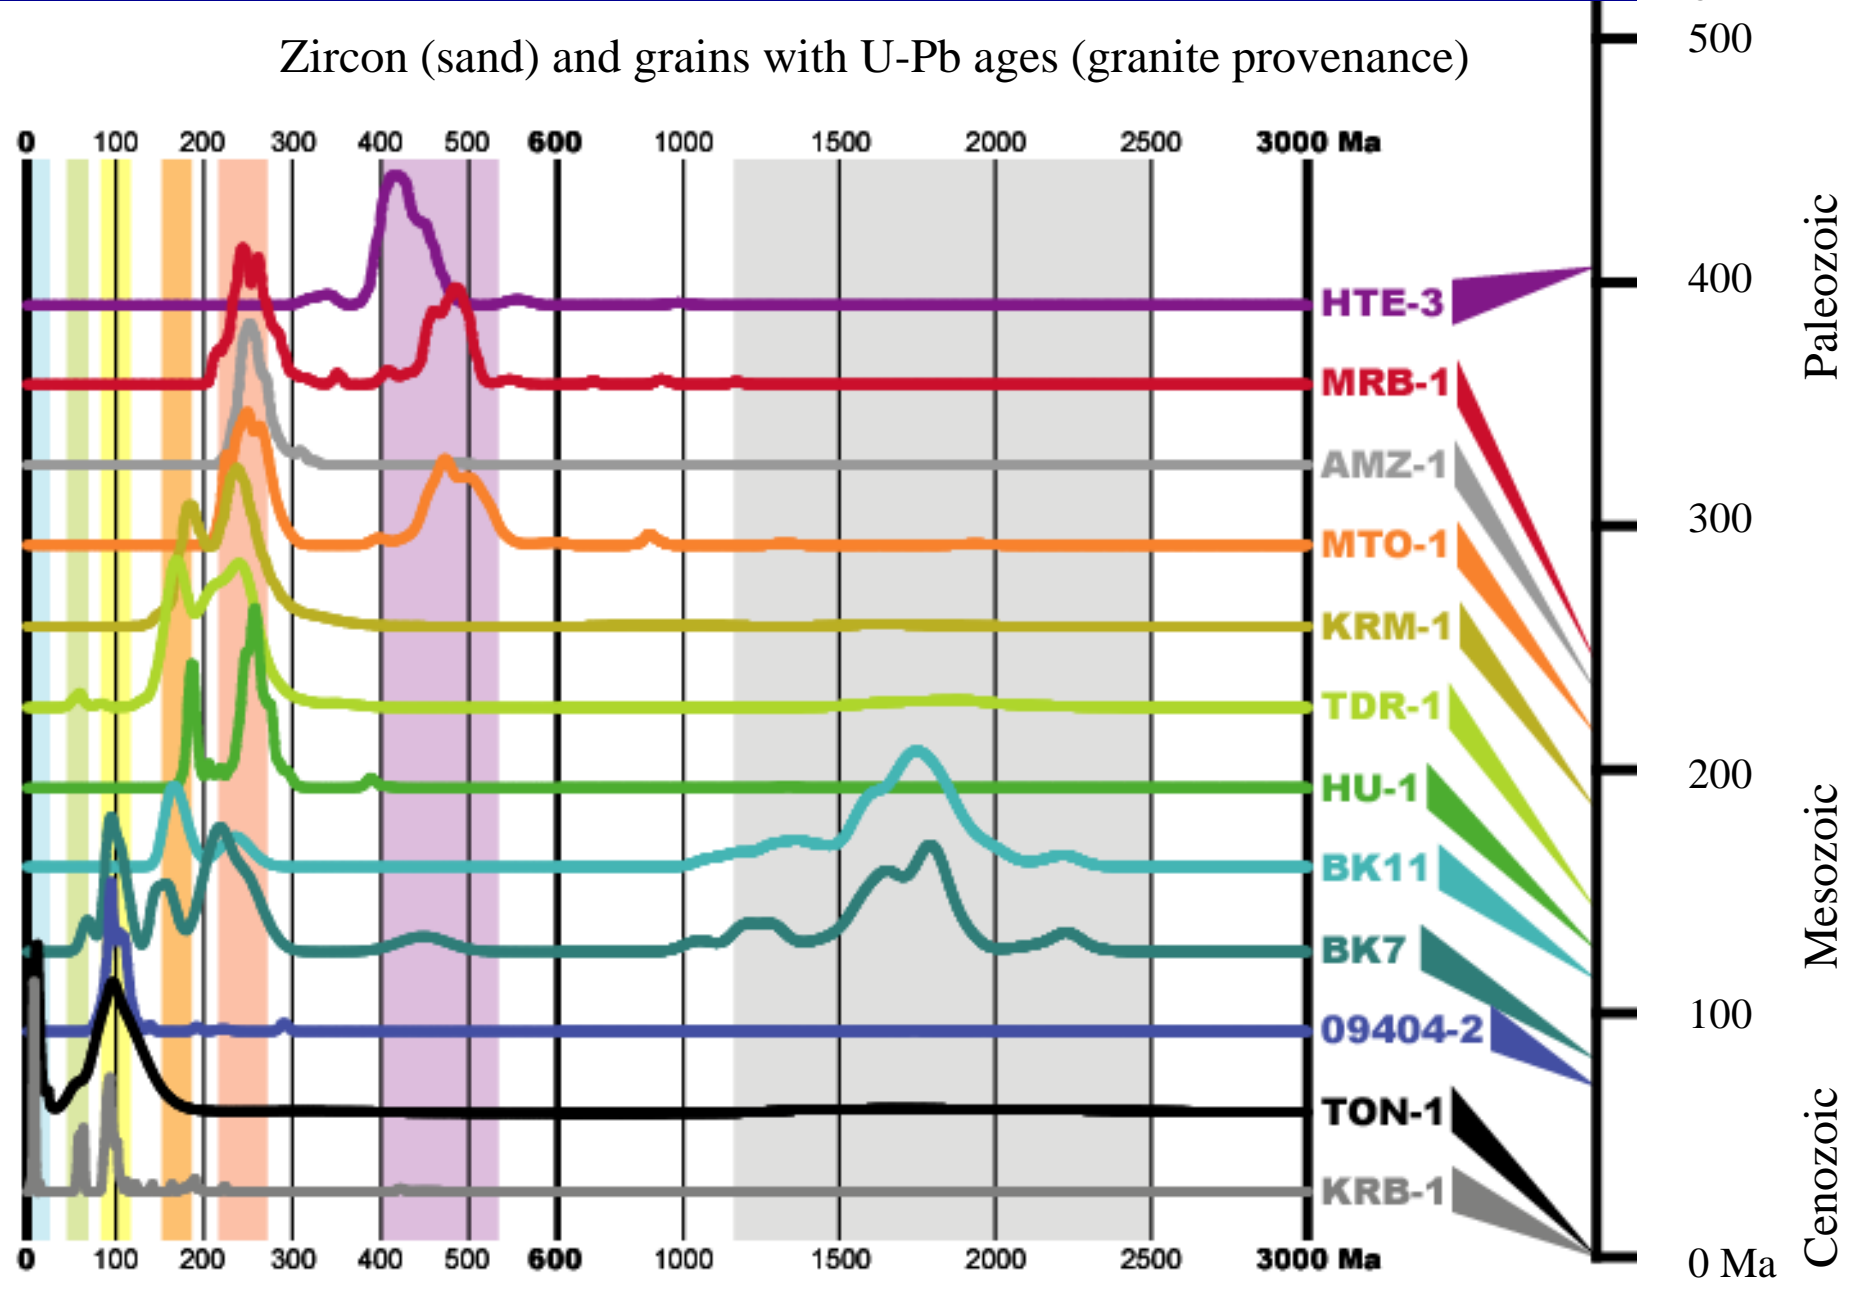

conundrum

disagreement between
elapsed time and
remaining continental
crust

Paleozoic: 290 m.y.
Mesozoic: 185 m.y.
Cenozoic: 65 m.y.

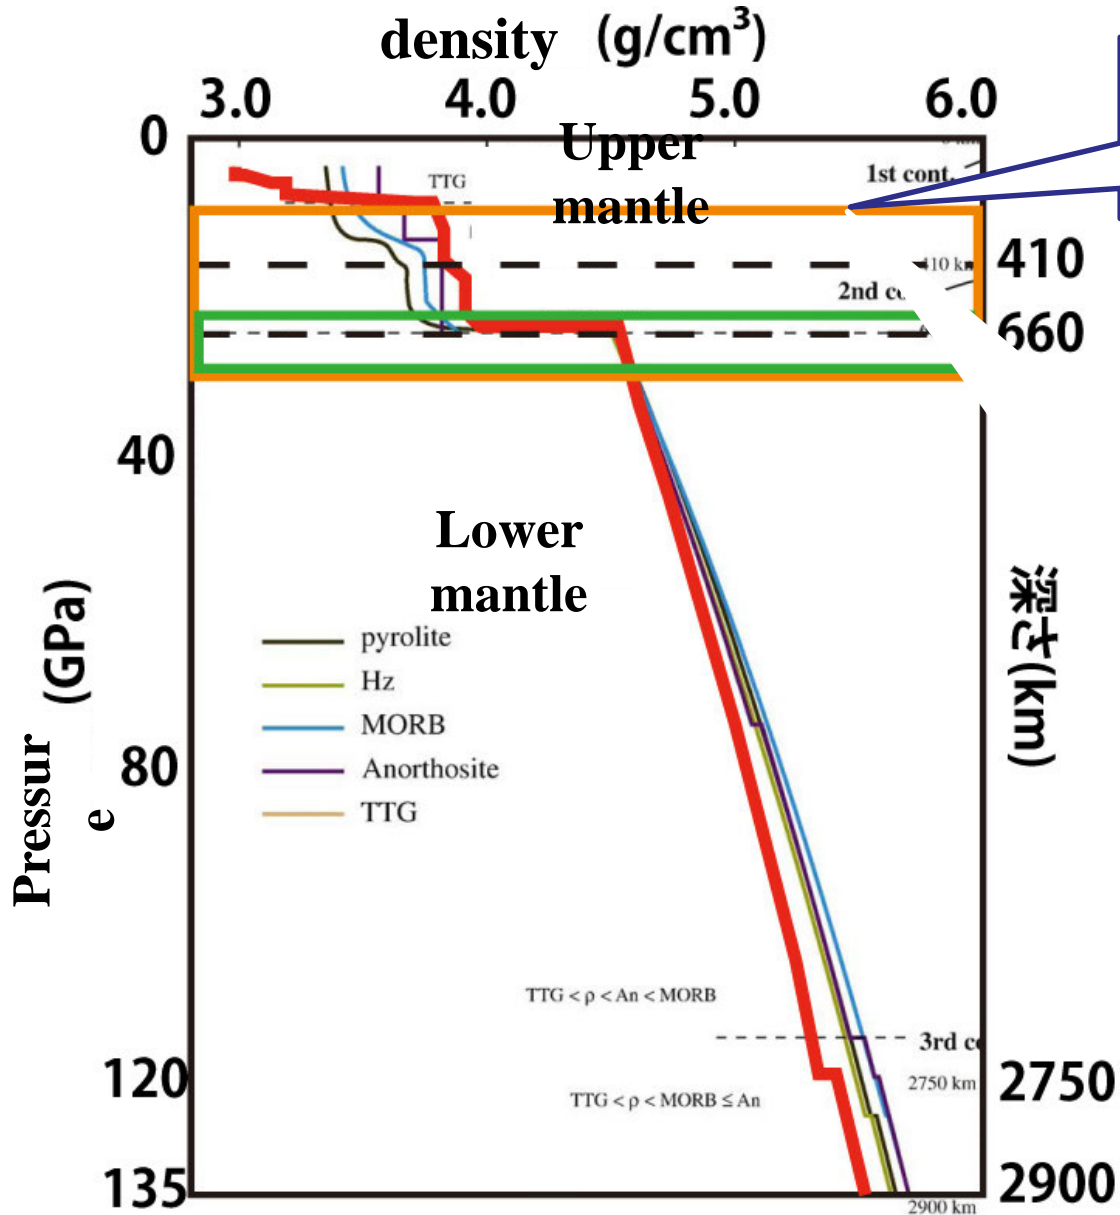

older arc granite belt:
exposed extensively, then gone....

Without vaporizing to the outer space,
to somewhere else?

Light-weighted continental (granitic) material
can subduct into mantle with heavy rocks??

Indication of the existence of second continent

At 300–800km depth, Granite becomes much denser than mantle peridotite

- Across the lower transition zone, seismic velocity (V_p , V_s) becomes faster than PREM
- May indicate the presence of 6-7 times of granitic crustal material in mantle transition zone.

First principle calculation (Kawai et al., 2009; 2010)

tectonic erosion

構造浸食

how to slim continents

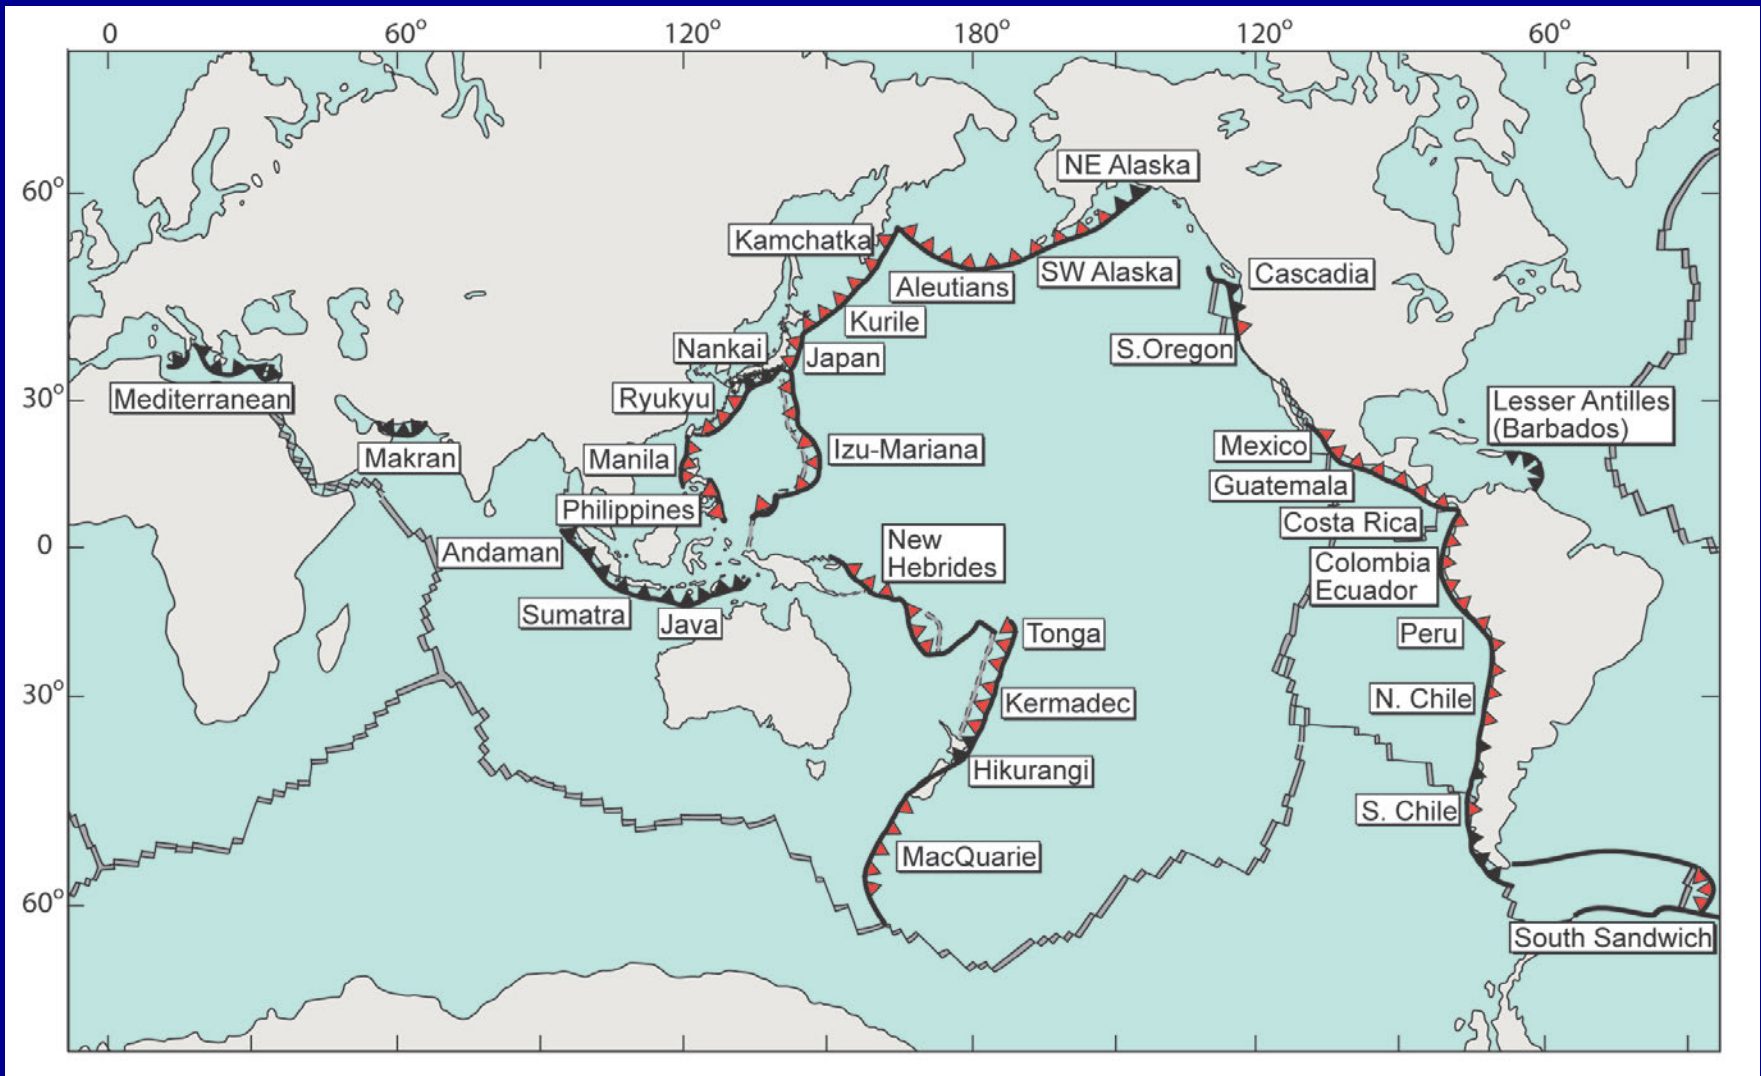

von Huene & Scholl (1990)

Seismic cross-section across the Japan Trench

Modern subduction zones in the world

△: Erosive (non-accreting) margins (~75%)

▲: Accreting margins (~25%)

(Scholl and von Huene, 2007; 2009)

tectonic erosion

Losing arc crust means disappearance of granitic continental crust.....

Accretionary growth I

Tectonic erosion I

Accretionary growth II

Tectonic erosion II

Where to dump
the lightest rocks
like granite
in solid Earth?

No worries,
we can bury
continents into
the mantle!

New view: another continent in mid-mantle (Maruyama, 2012)

Lost Atlantis??

Previously we imagined without doubt

- granitic continent. crust is more buoyant than mantle rocks
- low-density continents never subduct into mantle

Second continent:

accumulated continental material is 6 times of extant continents on surface
(Rino et al., 2007)

Another heat source for mantle convection

Tectonic erosion:

destruction of continent at subduction zone
(e.g. Scholl & von Huene, 2007)

Conclusions

- 1) Geology of Japan recorded the history of a Pacific continental margin that added continental crust, apparently for 400 km wide during the last 500 m.y.
- 2) Typical/general growth pattern of continental crust by active plate subduction, with growth and retreat, was demonstrated.
- 3) The main implication is in the burial of a large amount of continental crust (with high content of U and Th) into the mantle, which was totally overlooked for years.
- 4) The claimed second continent in mid-mantle may provide a possible hunting target for geoneutrino researchers.
